Extravasation injury may occur in 0.1–6.5% of patients receiving chemotherapy \(^1\) and up to 11% in pediatric patients receiving intravenous (IV) fluids” Ching and Wong (2017).

Abstract:

Extravasation injury may occur in 0.1–6.5% of patients receiving chemotherapy \(^1\) and up to 11% in pediatric patients receiving intravenous (IV) fluids. Furthermore, rates extending to 70% have been observed for neonates in hospital.\(^2\) Although most remain localized and heal spontaneously with conservative management, the sequelae of extravasation are often underestimated. A higher incidence in this age group, particularly in neonates, is because of small and fragile veins, requirement of IV lines over long periods of time, and inability to communicate clearly.
