

We describe here treatment approaches and treatment-related complications in 138 hospitalized children with disseminated Lyme disease” Chang et al (2017).

Abstract:

We describe here treatment approaches and treatment-related complications in 138 hospitalized children with disseminated Lyme disease. The patients who received parenteral antibiotics had a higher rate of complications than those who received oral therapy (15.4 vs 4.2 per 1000 days of therapy, respectively; $P < .05$). Oral therapy should be used preferentially if either route is supported by current guidelines.
