When considering a patient with factitious disorder as a candidate for infusion therapy, the clinician must be aware of the challenges associated with providing an invasive treatment to high-risk patients while promoting safety” McMillan (2020).

Abstract:

Factitious disorder, formerly known as Munchausen syndrome, is a type of mental illness in which patients fabricate symptoms to gain attention or sympathy. When considering a patient with factitious disorder as a candidate for infusion therapy, the clinician must be aware of the challenges associated with providing an invasive treatment to high-risk patients while promoting safety.
